Preliminary wing - optimization

In the preliminary wing analysis we have tested with VSAERO three airfoils on wing solo configuration

MH32, E216, FX63137

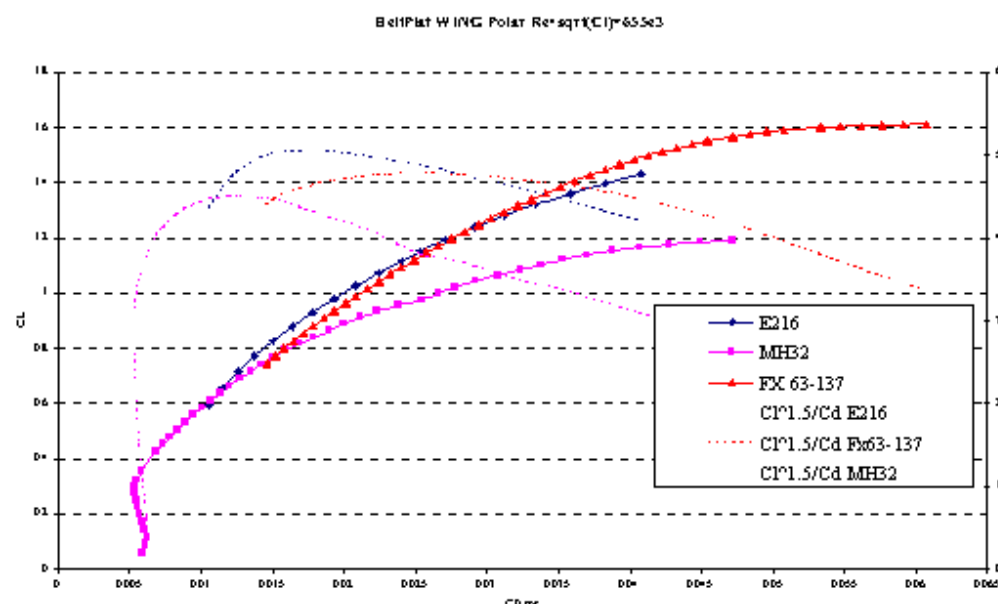

Figure 2 – HeliPlat Wing solo Polar

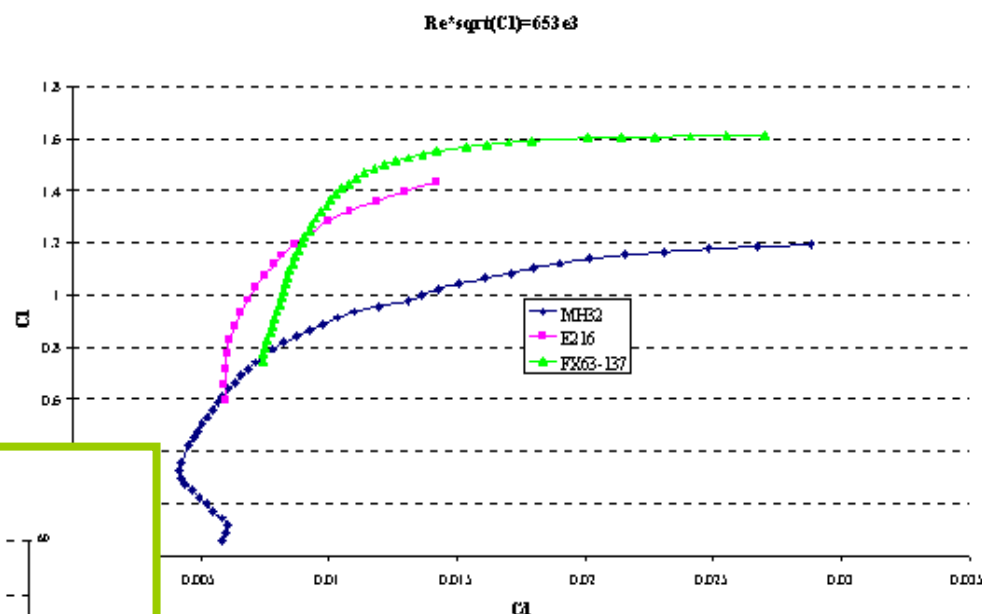

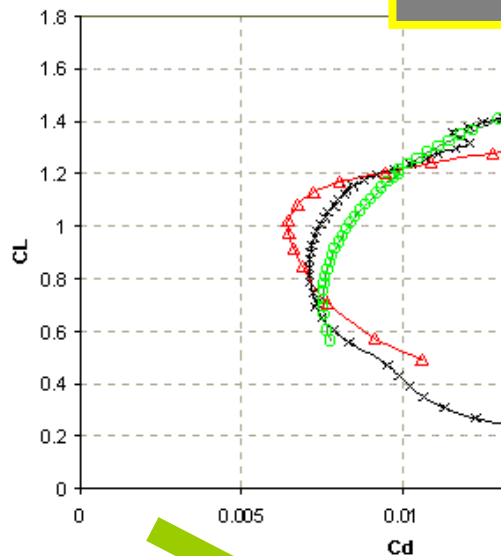

Figure 1 – Wing Profile Polar

E216 show a better compromise between the airfoil Drag and the induced wing Drag

combined effect

Effetto combinato Re=500000

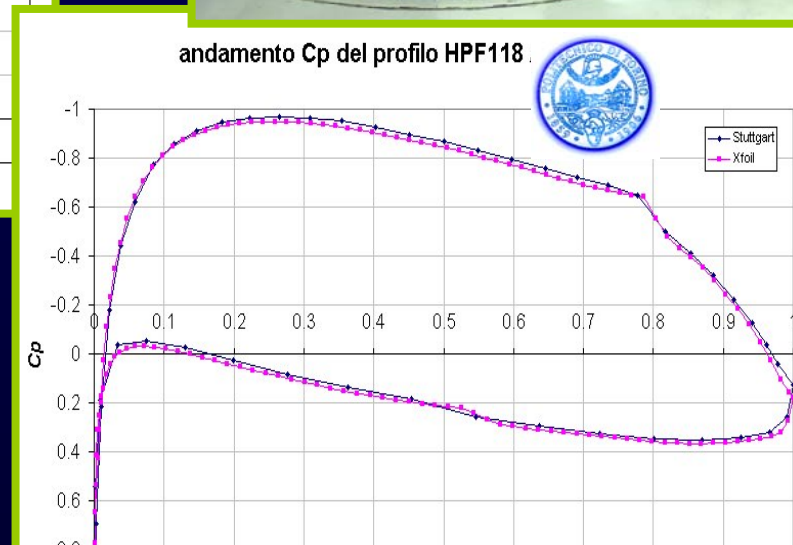

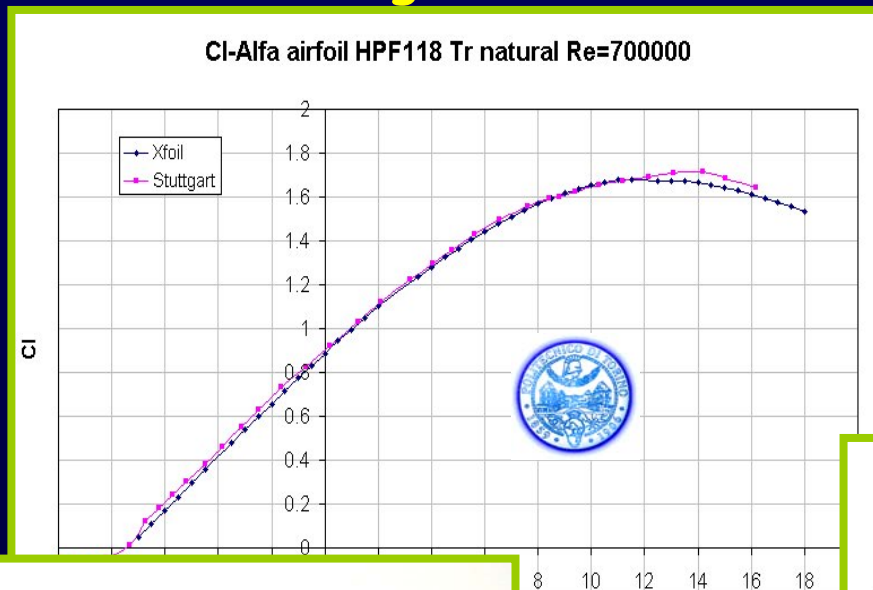

Heliplat®

Fluid Dynamics Specialist

By Using XFOIL, the optimal airfoil HPF118 has been designed instead of E216. The good performances of HPF118 are also demonstrated by experimental investigation in the Laminar Wind Tunnel in Stuttgart.

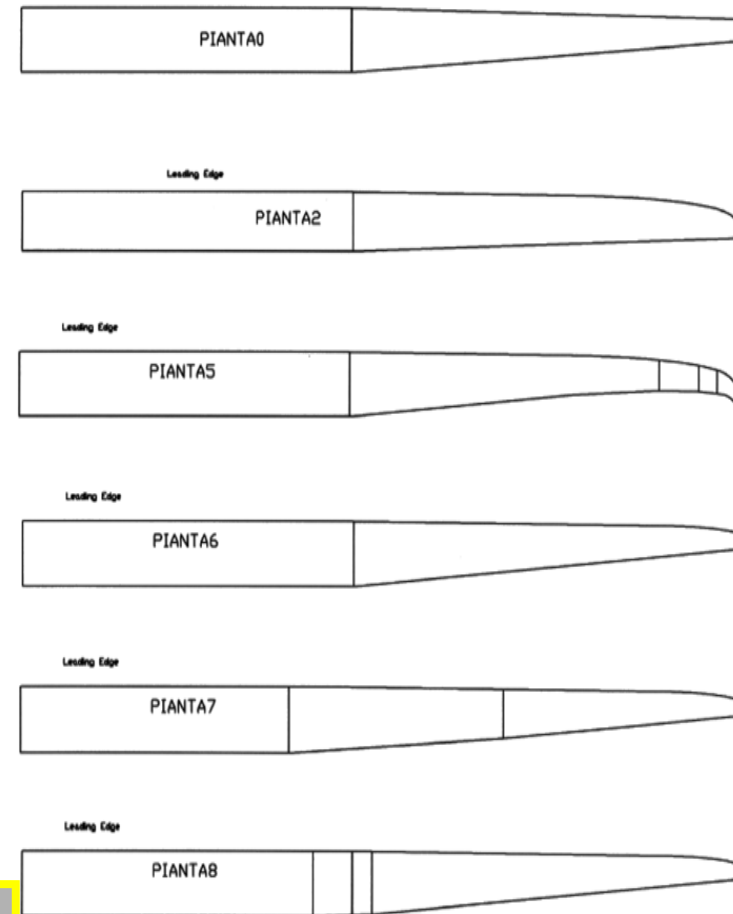

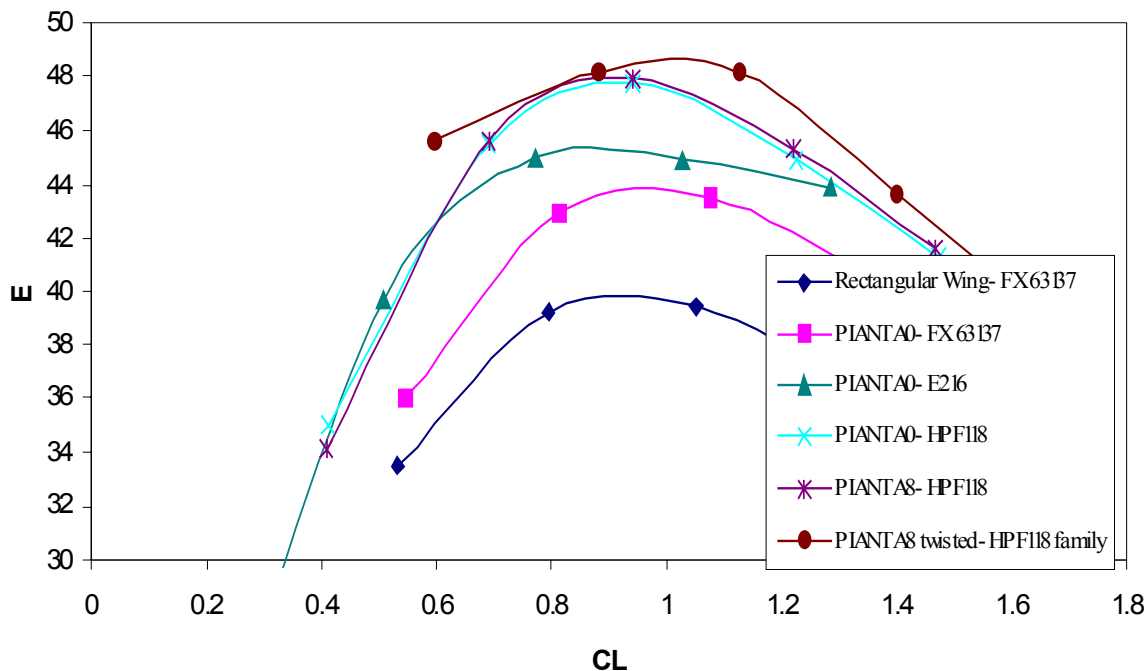

Heliplat®

Fluid Dynamics Specialist

The optimization of wing planform have the intention to minimize induced drag. Indeed it was found that some wing planforms increase the friction drag more than the induced drag reduction. Each wing have constant span and equal surface, i.e. $AR = \text{cost}$.

Aerodynamics Efficiency

Why we have choose to use Vsaero panel methods technology?

- Contain the right physics
- Handle complex & arbitrary geometry
- Resolve all important physical & geometric length scale
- Reliably accurate numerics
- Timely
- Properly validated
- Can be run many, many times

Conclusions

- Vsaero is an excellent tool in order to design the best package to fulfil the design targets.
- Good correlation between numeric and experimental data.
- calculation quickness
